

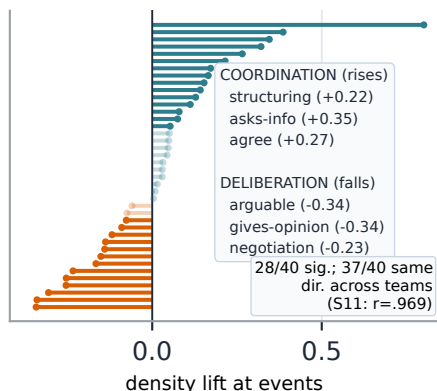

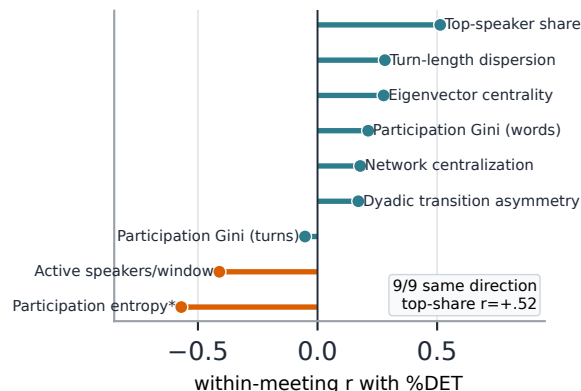

Figure 2 — Individual and team-level structure of communication reorganization

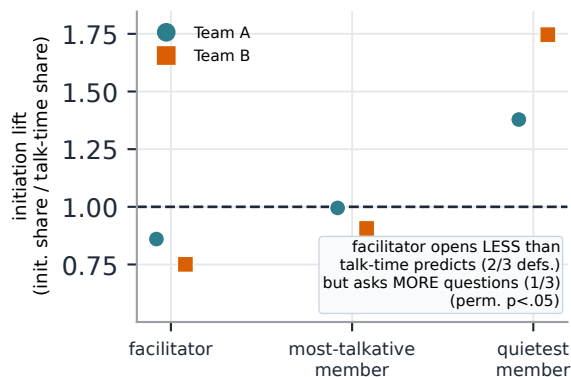

A. Content fingerprint (6 schemes, 40 categories)

B. Floor structure (F1 → F2)

C. Who opens the floor (S9)

D. Affective signature (S12)

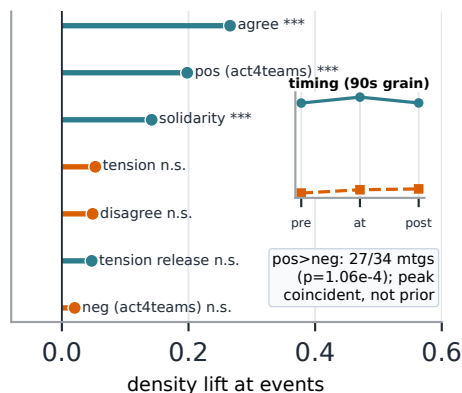

Figure 2. Individual and team-level structure (Study 2, with S9 and S12 corroborations). (A) Per-category event-vs-baseline density lift across six coding schemes (40 categories, BH-FDR); teal=coordination-type (rises), orange=deliberation-type (falls), faint=non-significant. Cross-team profile replication $r=.969$ (S11). (B) Nine coding-free floor/centralization measures at events vs baseline; all nine move in the same direction (floor equalizes, decentralizes), consistent with Edelsky's (1981) F1-to-F2 transition. (C) Initiation lift by speaker role; the external facilitator initiates fewer floor-taking and topic-opening events than their talk-time predicts (permutation $p<.01$) but MORE question-initiated events than predicted ($p=.01$) (S9). (D) Event-vs-baseline lift for eight affect codes (Bales IPA + act4teams pos/neg); agreement, positive affect, and solidarity rise significantly ($q<.001$); no negative code survives FDR; the positive signal peaks coincident with event onset (inset, not before or after (S12)).
