

A. Event-locked socioemotional lift

B. Timing within the event window

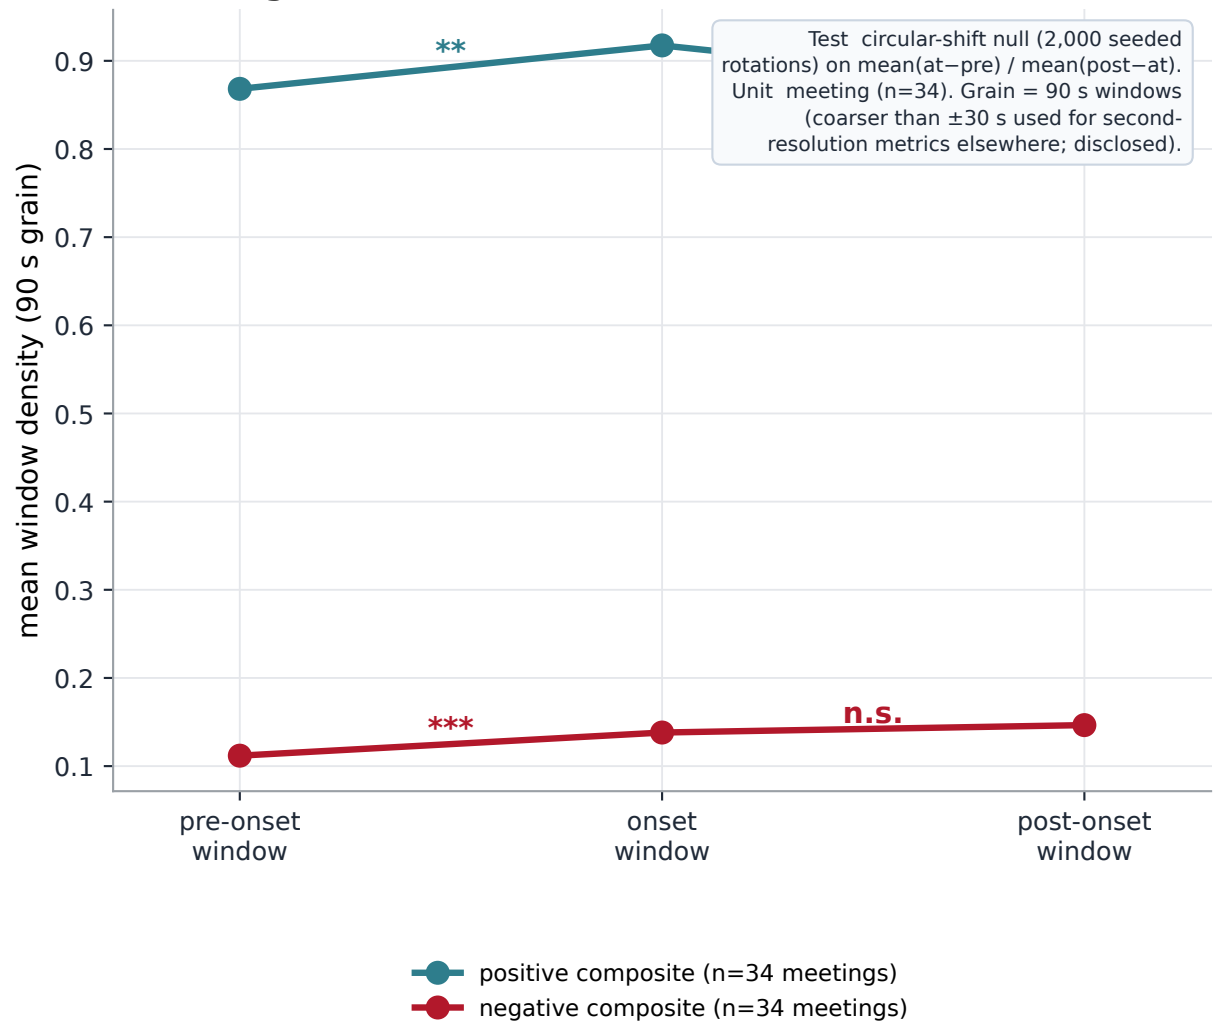

Figure 12. (A) Across the 8-category confirmatory socioemotional family (Bales IPA positive/negative quadrants + act4teams-full positive/negative facets), reorganization events are accompanied by a positive, not a negative, socioemotional signature: agreement, positive socio-emotional acts, and solidarity rise significantly (BH-FDR $q < .001-.0003$); disagreement/tension/antagonism do not survive FDR. (B) The positive signature is a sharp spike coincident with the event itself (rises pre $\rightarrow$ onset, falls onset $\rightarrow$ post, both $p < .02$ by circular-shift null) - not a before-the-fact lubricant nor an after-the-fact repair; the negative composite rises into the event but does not significantly recede afterward. Two attempted coding-free lexical markers (typed laughter conventions, exclamation density) returned null data in this ASR-transcribed, spoken corpus and are not plotted (see RESULTS.md).
