

Study 10 — A real but modest early-warning signature: population-level regularity, not a reliable single-event alarm

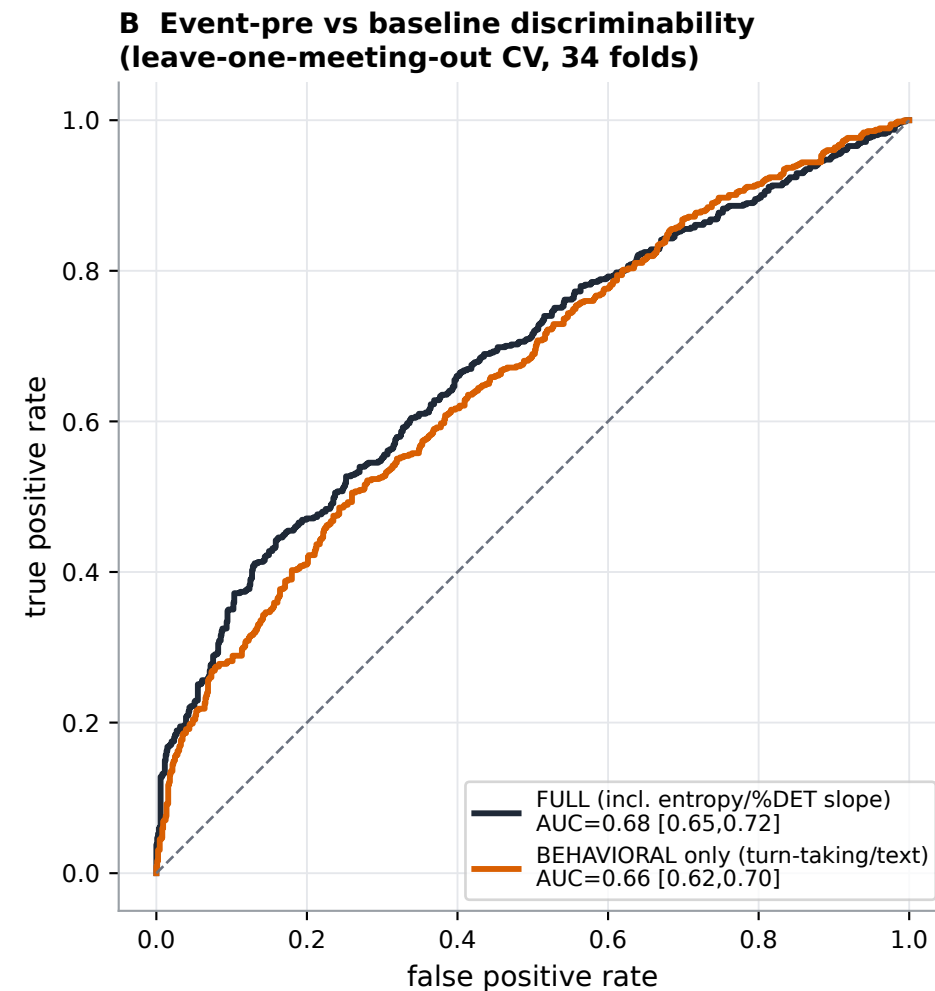

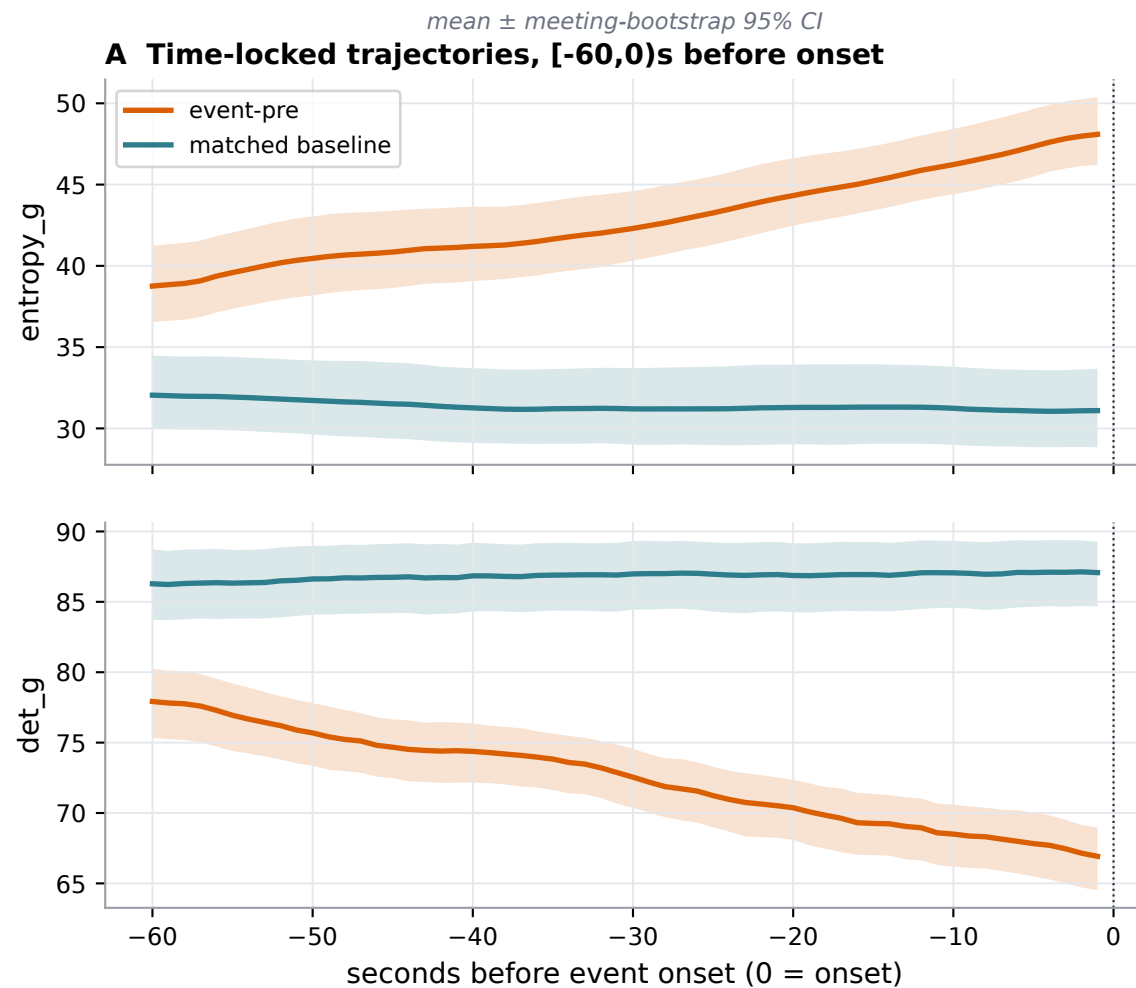

Figure 10. (A) Entropy rises / %DET falls approaching an event vs a flat matched baseline — expected in part by construction (approaching a local extremum). (B) Leave-one-meeting-out discriminability is modest even restricting to turn-taking/text features with no mechanical tie to the metric (AUC $\approx$ 0.66) — a real, population-level regularity (meeting-level paired effects are large, rank-biserial $\approx$ 0.9-1.0) but not a reliable single-event alarm; most individual events show no detectable precursor by a 1-SD criterion.
