

**Figure 3 — Temporal structure of communication reorganization**

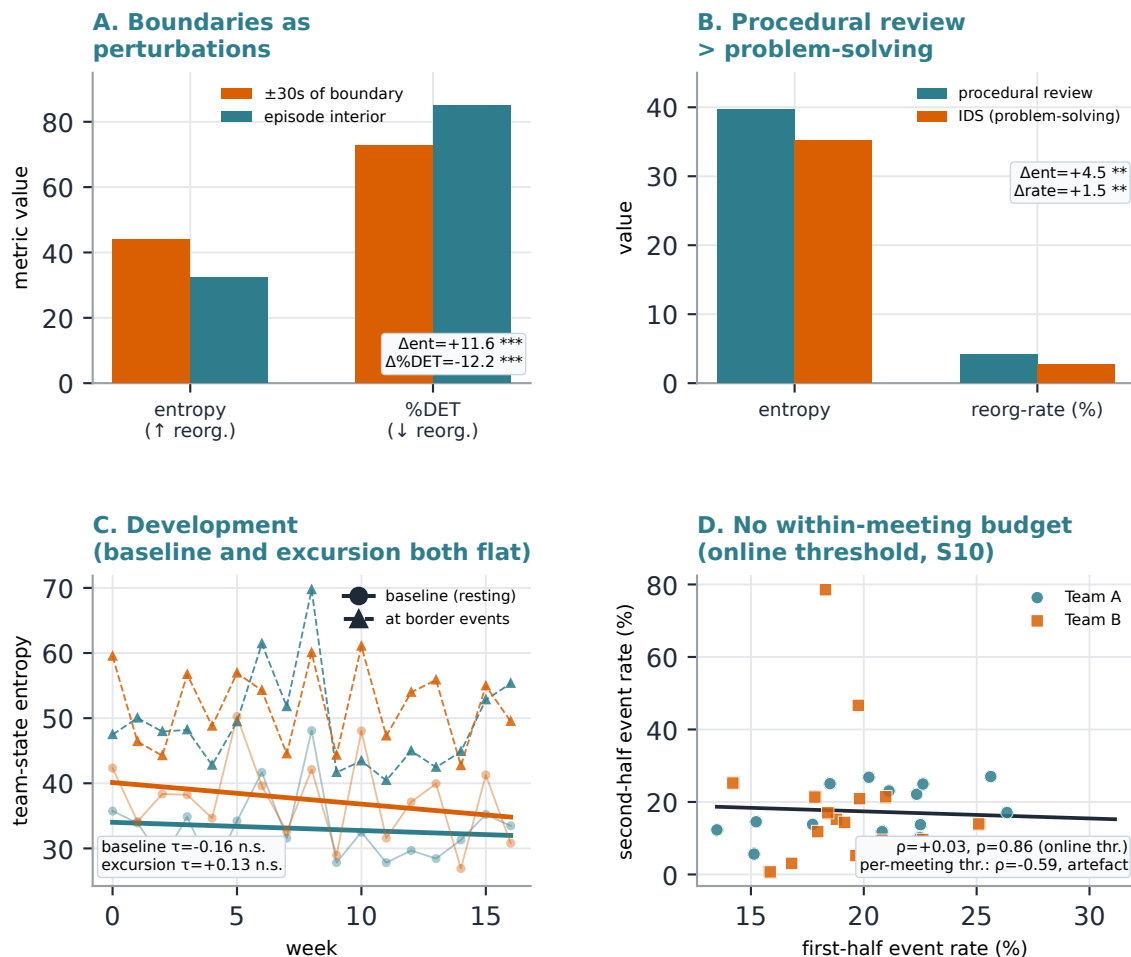

Figure 3. Temporal structure (Studies 6, 7; extended by S10). (A) Mean entropy and %DET in  $\pm 30s$  windows centered on topic-episode boundaries vs matched interior windows (paired Wilcoxon, non-circular: boundaries from content, metrics from turn-taking). (B) Reorganization rate and entropy by EOS Level 10 protocol stage; procedural review (teal) reorganizes significantly more than problem-solving (IDS; orange). (C) Per-meeting baseline entropy and above-baseline excursion over ~26 weeks (Kendall tau); after correcting the speaker count for a transcription-tool line in the ten latest meetings, neither the baseline nor the excursion trends significantly - the event is developmentally stereotyped in size and its resting point does not drift (S11). (D) First-half vs second-half reorganization rate with an online event threshold (first-half statistics only); the association is null. The strong negative association obtained with a whole-meeting threshold is reproduced by a circular-shift null, i.e. it is an artefact of that threshold; the data do not support a within-meeting reorganization budget (S10).
