

Study 11 — Cross-team replication ledger: does Team B's effect match Team A's, in sign and magnitude?

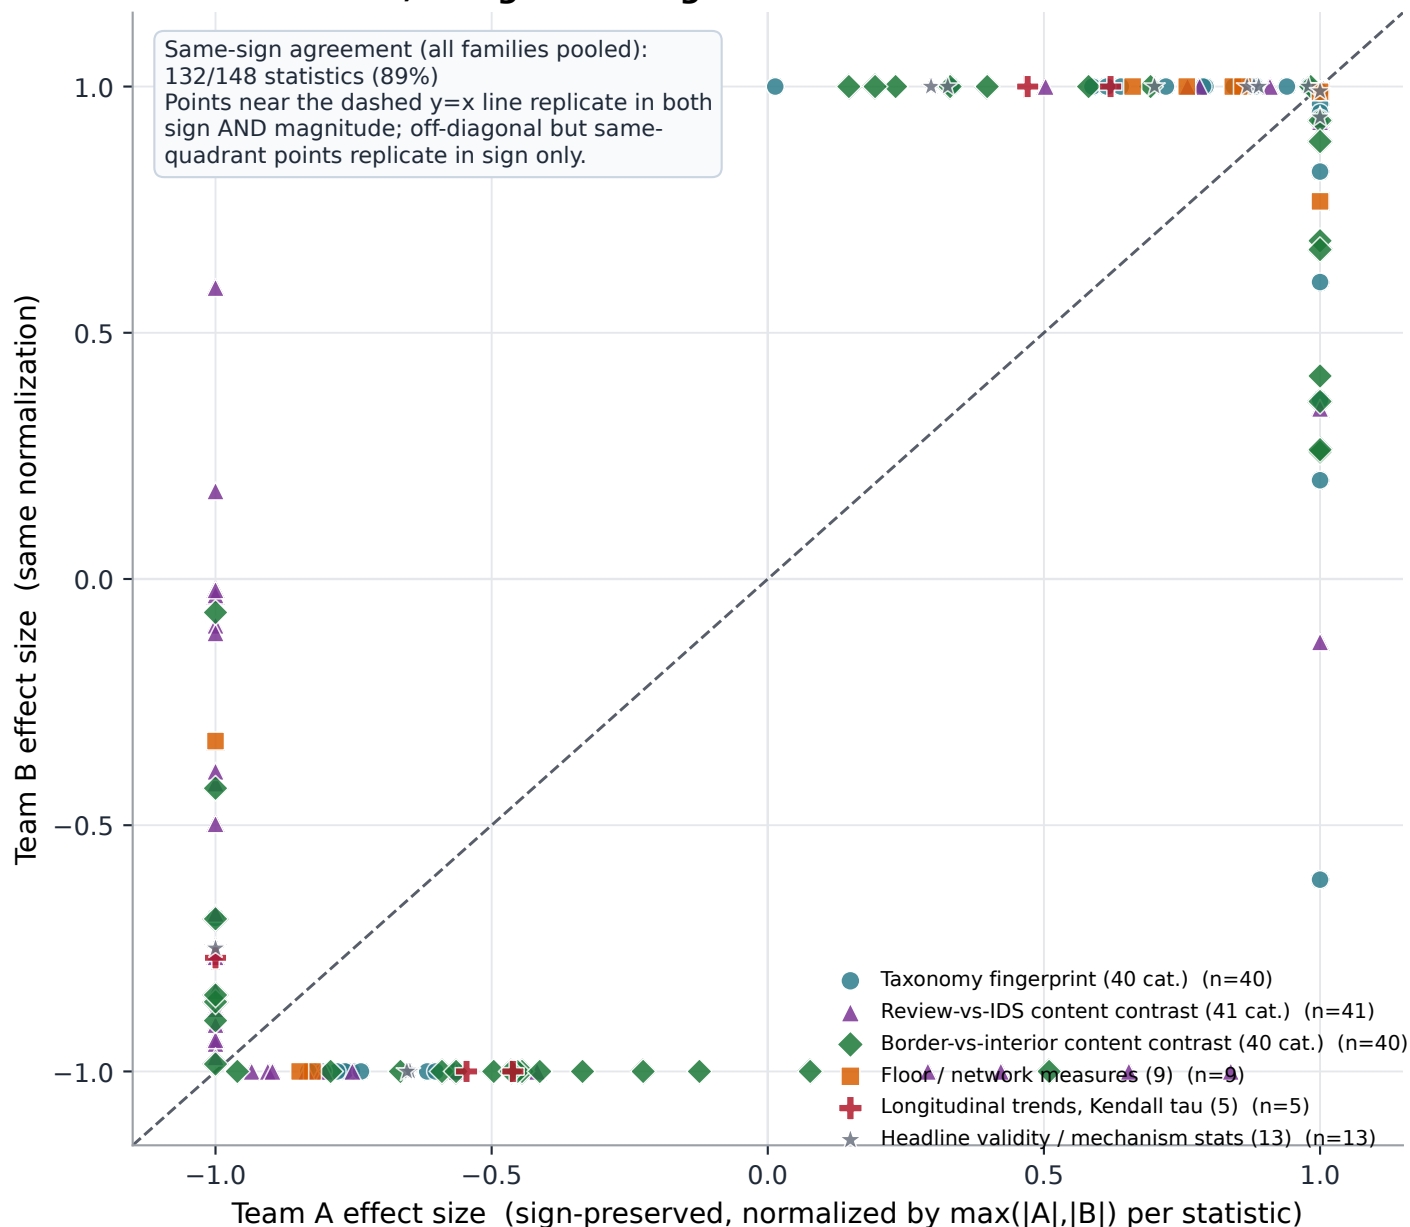

Figure 11. $n = 148$ headline statistics spanning validity checks, content-taxonomy profiles, floor-structure measures, and longitudinal trends, each computed independently in Team A and Team B using identical methods (Studies 1-10). Values are normalized per statistic (divide both teams' estimates by whichever is larger in magnitude, preserving sign), so the $y=x$ line represents perfect cross-team replication and quadrant membership (top-right / bottom-left vs. top-left / bottom-right) directly shows sign agreement. One explicitly flagged sign non-replication (facilitator-share longitudinal trend) sits in an off-diagonal quadrant; a second flagged non-replication (initiator-rank stability) agrees in sign but differs sharply in magnitude, among the gray stars/plus markers.
